**Abstract**

**medialatinitas.eu** is a lightweight web application which integrates dictionaries, corpora and encyclopaedic resources for Latin. The integration takes places principally on the level of the user-friendly interface, so no explicit links between resources are provided. The main objectives of **medialatinitas.eu** are: improving access to distributed data; challenging separation of linguistic and encyclopaedic information in lexicographic description; compensating for deficiencies of existing lexicographic resources; building a community of users who apply computational methods in their study of Latin texts.

As for the architecture, **medialatinitas.eu** is implemented as a mashup application: the user’s query (as of now, only lemma search is supported) is processed and despatched to both local and distant services (RESTful APIs, SPARQL endpoints); the results are subsequently returned and displayed on the main page as a set of separate widgets. The widgets may contain short concordance lines and tables, but special attention has been given to alternative ways of content presentation, namely charts and visualisations. The widgets are provided with rich graphical hints and hold together thanks to such narrative devices as interpretative notes or explicative commentary. As a whole the widgets contribute to extensive description of Latin lemmas according to their grammatical, semantic and cultural properties.

**Keywords:** lexicographic mashup; data reuse and integration; visualisation; dictionary-corpus interface; Medieval Latin

**1. Introduction**

Latin was one of the most widely used languages in European history. In its spoken and written form it was the language of daily communication, law, literature, and science for over fifteen centuries on the territory stretching from Spain through Germany to Poland and from Sweden through Croatia to Italy. This geographical, chronological and functional variation is reflected in a large number of texts which, in turn, gave rise to a vast body of secondary literature of which dictionaries form an essential part.

The multifarious resources, even if partly digitised by now, remain still widely dispersed and do not easily lend themselves to integrated search. Moreover, separate electronic text collections usually cover only small proportion of the texts preserved to our times and do not have any pretensions to representativeness. Often, they would also be available only through an interface that does not allow for any subtler
query. As for the electronic dictionaries, their selective spatio-temporal coverage, multilingual definitions, and differing editorial styles make that they cannot be said to account for Latin development in any systematic way if consulted separately.

medialatinitas.eu is a web application which aims for a meaningful integration of textual, lexicographic and encyclopaedic resources for Latin through a user-friendly and attractive interface. It is also an attempt to generate a coherent narrative from incomplete data despite variety of technologies in use. The integration is said to be shallow, since the heterogeneous content (dictionaries, encyclopaedias and corpora) has been linked only to the degree needed for its unified query and retrieval. It takes place, then, at the level of the web interface which, thus, constitutes presentational layer and a point of access to the services running in the background. At the moment, medialatinitas.eu is intended in particular for academic audience (lexicographers, linguists, historians etc.), but teachers and students of the medieval literature should also find it useful.

2. Data, Goals, Design

2.1 What to integrate: data

medialatinitas.eu makes extensive use of the existing digital resources for the Latin language and culture. The data which are going to be integrated within the web application may be roughly divided into three groups (Figure 1):

1) lexicographic resources: dictionaries of Classical, Medieval and Modern Latin, both academic (e.g. Novum Glossarium Mediae Latinitatis, Lexicon Mediae et Infimae Latinitatis Polonorum) and community-based (e.g. Latin Wiktionary); dictionaries and thesauri of ancient and medieval placenames, gazetteers (Pelagios Project, Orbis Latinus, Getty Thesaurus of Geographic Names, GeoNames);

2) corpora (e.g. Fontes. Corpus of Polish Medieval Latin, Croatiae Auctores Latinî) and text collections (e.g. Perseus Project, Patrologia Latina etc.);
3) encyclopaedic resources: encyclopaedias (Wikipedia, in particular its Latin version), paremiological resources (Latin Wiktionary), document and image repositories (Europeana), library catalogues (Internet Archive, Open Library), lists of medieval authors (e.g. Novum Glossarium, VIAF), hybrid resources (e.g. BabelNet).

Regarding their origin, the vast majority of resources were created by external institutions and only very few are the result of in-house projects (Novum Glossarium, LMILP, Fontes). As one may suppose, this and the format in which the data are generated, imply different strategies of access and reuse, and contribute to the complexity of the integration task, as the resources are mostly exploited “as they are”.¹ In-house dictionaries come originally as TEI-conformant XML files based on a shared encoding scheme. Both external and in-house corpora were delivered as XML files containing lightweight document mark-up for meta-data and structural features of the text. Each corpus text was tokenised and annotated with part-of-speech (PoS) and lemma labels. The annotation was performed using the TreeTagger (Schmid 1994). The Latin parameter file that the tagger requires was based mostly on the texts from the Perseus Digital Library and the Index Thomisticus; however, this is likely to be changed in the nearest future, once the work on the Medieval Latin parameter file comes to an end (Omnia Project TreeTagger).

The majority of external resources are exploited through their public RESTful APIs or SPARQL endpoints; so the medialatinitas.eu remains to some degree agnostic of the original data formats or encoding schemes (Figure 2). Regardless of their origin, even the locally hosted data are exposed to the web application through the APIs:

- dictionaries deployed in an eXist-db instance are exposed through respective RESTful API;

- textual corpora are deployed in a CQPWeb (Hardie, 2012) instance; since for the moment CQPWeb does not offer a web API, it is used only as an advanced corpus research tool;

- OCR texts and less-structured text collections are stored in eXist-db Lucene-based indexes and exposed through a RESTful API.

Yet, the role of locally running services is by no means limited to only exposing data, since they also serve to enrich, compute on and prepare data for subsequent display:

- the WikiLexicographica (Bon & Nowak, 2013), an implementation of the Semantic MediaWiki (Krötzhc et al., 2006), combines dictionaries with geographical and chronological dimension, thus enabling rich data representation;

- an R (R Core Team, 2015) session is exposed to the web application through the OpenCPU API (Ooms, 2014) and permits computation on corpus and lexicography

¹ For explanation, see below.
resources; *rcqp* package (Desgraupes & Loiseau, 2012) is used to connect to the *CQP* engine; A. Guerreau’s scripts for lexical statistics (*Medialatinitas Github*) allow to find co-occurrences of the lemma in the corpus, while S. Evert’s *wordspace* package (Evert, 2014) is employed to calculate word similarities based on their distributional features.

### 2.2 Why integrate: objectives?

*medialatinitas.eu* was created in order to:

1) improve access to distributed resources and facilitate the dictionary writing process;

2) stimulate research on Medieval Latin vocabulary through linked resources and popularise an innovative approach to the study of Latin text;

3) integrate a community of experienced and early-stage researchers who want to apply computational methods in Latin philology, history and linguistics.
2.2.1 User’s commodity

On the most intuitive level, handling scattered resources results in losing time and energy. This primarily stems from the very fact that the data are stored in different locations. Not only do the users have to consult multiple web pages, but they can never guarantee the accessibility of the resource of their choice, as its availability depends entirely on whether the distant service is actually running. Even if it is, each service or repository the user has to consult forces them to respectively adapt their search strategy, remind of the query syntax or verify the integrity of the data. The latter, in particular, may often be difficult to assess, as many databases or text collections still lack appropriate documentation which would explain text or dictionary origin, its scope, data encoding scheme adopted and so on. In the worst scenario, a scarcity of information would increase the disadvantages inherent in many non-research-driven web resources, such as a lack of quality control, unclear or dubious choice principles, fragmentary and subjective character.

2.2.2 Answering old and asking new research questions

Yet, the user convenience, albeit important, is not the main objective of the medialatinitas.eu project. The principle that underpins the design of the present web application is to challenge the separation of knowledge components that should effectively cooperate in comprehension of the Medieval Latin text and culture. To achieve this goal and to compensate for the deficiencies each separate resource presents, medialatinitas.eu enables their concurrent, yet meaningful retrieval, and intertwines them in order to construct a coherent account of a word’s meaning potential, its grammatical and syntactical properties and cultural function. At the same time, medialatinitas.eu promotes alternative forms of access to linguistic data (charts, maps etc.) and their reuse in new research contexts.

At a more specific level, medialatinitas.eu builds upon its linguistic content by addressing those issues which are either typical of a lexicography description in general or which affect Medieval Latin dictionaries in particular, namely:

1) limited account of variation of the Latin vocabulary;

2) limited or inadequate frequency information which is based mainly on manual excerption of the linguistic evidence;

3) purely linguistic approach to sense definition.

Numerous benefits that come from closer integration of lexicographic and corpus resources need not be enumerated here. Within the main interface of the medialatinitas.eu corpus, data are used to shed more light on the distributional properties of the Latin vocabulary. These are handled unsatisfactorily in the Medieval Latin dictionaries which did not adopt any coherent system of marking, for example, word frequency, except for such imprecise labels as ‘more often’ or ‘very
often’. This, in turn, makes distinguishing between widespread and limited phenomena often a challenging task, as the latter (hapax legomena included) are being traditionally given relatively more space than high-frequency lemmas. Moreover, existing evaluation of the frequency of word or grammatical/syntactical pattern is far from ideal, since it is based on evidence which was manually retrieved from the sources (Guerreau-Jalabert & Bon, 2010; Bon, in print). The dictionaries also often fail to provide an adequate account of the diachronic, diatopic and genological features of the word use. On the one hand, they would often overestimate stability of semantic or grammatical patterns through the ages, while neglecting their changing function and dynamic distribution across the text genres. On the other hand, the available dictionaries (some of them still in progress) cover neither all periods nor all geographical zones of Latin development. Targeted corpus query may compensate for their shortcomings in this regard.

Equally important are reasons for closer integration of encyclopaedic data. medialatinitas.eu draws on the research of modern linguistic theory which demonstrates that the distinction between linguistic competence and real-world knowledge is not as clear-cut as the lexicographic practice shows (Geeraerts, 2000). medialatinitas.eu searches, then, for a compromise between the rigour of purely linguistic definition and the fact that the users of historical dictionary usually need more information when trying to understand ancient text, as the amount of the shared cultural background is necessarily significantly limited. This is the more remarkable, as Medieval Latin was for centuries the language of scientific, theological and philosophical writing, so exhaustive dictionaries (as the majority of those currently in print are) inevitably have to deal with this terminological richness². Although medieval terminology calls for different sense defining strategy than one applied in general lexicography, one often comes across definitions that, due to their purely linguistic character, are virtually void of any explicative potential. Meaningful reuse of encyclopaedic resources in the medialatinitas.eu application will help to tackle such specific cases and enrich dictionary content in general.

Finally, a closer integration of encyclopaedic and lexicographic data is desired for practical reasons. A good example in that respect might be proper names which are traditionally excluded from Medieval Latin general dictionaries. Yet, the correct decoding of place or personal names is crucial for understanding ancient text and constructing its referential layer. As a result, the readers of a medieval author will often find themselves consulting dictionaries and encyclopaedias at the same time. Aside from user convenience, however, including proper names will be of benefit, for instance, when describing common nouns if the latter are motivated by the former or vice versa (e.g. aqua ‘water’ is a component of many place names), etc.

2.2.3 Building a community of users and developers

²It makes some researchers claim that the Medieval Latin language was practically a special language (Bon, 2013).
Finally, the present work aims to integrate a community of developers and researchers. Although there now exists an active community of digital medievalists and the number of researchers who apply computational methods in their work on medieval texts has been steadily growing, until now no large-scale effort has been undertaken in order to integrate distributed data or to help developers embed their code snippets into a larger application. The same is true of pedagogical resources: despite numerous individual initiatives that have been launched (e.g. on-line bibliographies etc.), researchers willing to exploit automatic methods in their work cannot refer to any set of guidelines which would be appropriate for Latin text processing and query. This is why medialatinitas.eu will enable users to contribute their widgets\(^3\) as R and JavaScript code snippets responsible for single, yet self-contained functionality. Finally, the knowledge base that will constitute an important part of the medialatinitas.eu\(^4\) will provide users, on the one hand, with a curated collection of guidelines, showcases and links, and, on the other hand, with a complete description of digital medievalists' workflow - from the OCR to the corpus query.

2.3 How to integrate: application design and architecture

In the current development stage, medialatinitas.eu sticks with an integration model that could be characterised as ‘shallow’. The word is, however, used in the pregnant sense, as it is meant to describe implementation which is shallow, lightweight and agile at the same time.

The present integration model is called shallow, firstly because the data are not provided any explicit links and integration takes place principally in the application user interface (UI). As for now, virtually no effort has been put into harmonising different classes of resources, also same-class data are stored or dynamically queried “as they are”. Dictionaries, corpora and encyclopaedias do not refer to any common system of identifiers; therefore, for example, there is no formal connection established between the dictionary headword AQUA ‘water’, the lemma AQUA in the annotated corpus, and the Latin Wikipedia article for AQUA. As was already said, the same applies for same-class data, so, for instance, there is no inherent mapping between the entry AQUA in the DuCange’s *Glossarium mediae et infimae latinitatis* and its equivalent in the *LMILP*; similarly, there exists no explicit link between two identical lemma labels in separate corpora, if they have been annotated with different lemma sets. Ad-hoc equivalence between two dictionary headwords or lemmatised word forms is established if they have an identical orthographic form and share a PoS label. Other resources are currently retrieved based on a simple full-text query.

Secondly, medialatinitas.eu is designed as a three-level deep application (Figure 3) which offers the user to look up, for each lemma: 1) a general overlook; 2) an extended view; 3) an advanced view.

---

\(^3\) See below.

\(^4\) The knowledge base is beyond the scope of the present paper.
I) When visiting the main page, the user initially comes across a simple search form. Once the query phrase is specified (currently only lemma search is supported), it is next despatched to locally and remotely running services and APIs. The returned results are processed and, subsequently, displayed on the same page. Its layout is built around a grid system and consists of a series of separate widgets, each responsible for displaying some portion of information about the word in question. As a whole, the widgets contribute to a general, yet varied outlook of the word meaning, its linguistic properties and distribution. The widgets that have been implemented so far present, for instance: 1) short excerpts from definitions of the Classical and Medieval Latin dictionaries; 2) short extracts from corpora concordances; 3) selected morpho-syntactic properties (inflectional type, gender, tense or case endings etc.) of the word (retrieved from the electronic dictionaries); 4) distribution of word forms in the corpora; 5) diachronic and genological distribution of the lemma; 6) co-occurring terms in selected corpora; 7) similar words in selected corpora; 8) translations and similar terms (retrieved from the BabelNet); 9) links to the Latin Wikipedia pages whose text contains the word in question; 10) list of quotations which contain the searched lemma (retrieved from the Latin Wiktionary); 11) list of titles of literary works which contain the lemma (retrieved from the Internet Archive); 12) list of images (Figure 4) whose description contains the lemma (retrieved from the Europeana); 13) map of the place names (Figure 5) that contain the lemma (retrieved from the Pelagios Project, Getty Thesaurus of Geographic Names and GeoNames).

5 Single Page Application (SPA) model of web application design is adopted here.
medialatinitas.eu employs various forms of data display; widgets are, thus, implemented as tables (1–3, 8) or lists (9–12), but also as charts, visualisations (4–7) and maps (13).

II) the extended view, which is beyond the scope of the present paper, is accessible upon clicking on any of the main page widgets and offers a more detailed and focused perspective on the selected properties of the lemma. For the moment, only shiny-based (Chang et al., 2015) dashboard for lexical statistics has been developed.

III) the native application (CQPweb, eXist-db, R shiny interface etc.) is accessible
from the extended view and constitutes the deepest layer of the medialatinitas.eu web interface.

The present application can be considered as lightweight, as there is no intention for it to become a complete virtual research environment. It is conceived as a modular platform that allows rapidly plugging in new widgets and testing dynamically alternative modes of linguistic data representation. Because it eventually always refers the users to a native application, there is no ambition to replace any existing software, as it is believed that such mature tools as, for instance, CQPweb, already offer an exceptional set of features that one can most effectively build on. As a result, medialatinitas.eu is agile, since it is open to further expansion and should change according to the research interest and needs of its users and developers.

3. Discussion

3.1 medialatinitas.eu as a mashup application

In its design principle, medialatinitas.eu most resembles a mashup, which is defined as “a composite application developed starting from reusable data, application logic, and/or user interfaces typically, but not mandatorily, sourced from the Web” (Daniel & Matera, 2014: 3). It is ‘composite’, as it integrates data from more than one web service, each of which is a full-blown web application or a SPARQL endpoint. Following Daniel and Matera’s classification, medialatinitas.eu may be further described:

- regarding its “composition”, as a hybrid mashup, for the integration takes place both in the application logic and in the UI layer;

- regarding its “domain” or purpose, as a scientific, discovery-driven mashup;

- regarding “environment” or “deployment context”, as a web mashup in which logic layer is distributed over client and server: whenever a small data portion is involved, the client application written in AngularJS is responsible for processing Ajax calls, computing on their results and presenting them; however, once larger datasets come into play, especially when the user switches from a general view to the more specific one or when heavy calculation is to be applied, the burden of processing shifts towards the server and the client need only consider the visualisation of the returned data.

The user’s lemma query is passed to a mediator which subsequently transfers it to a series of wrappers. These, in turn, execute API calls and return back the results. The mediator, then, tackles the syntactic heterogeneity of the data, while wrappers deal with the idiosyncrasies of each source, thus resolving schematic heterogeneity. The

6 The use of this term is distantly inspired by the notion of agile software development.
problem of semantic heterogeneity of the data remains, as aforementioned, unresolved and this needs to be addressed in the nearest future by compiling a canonical list of lemmas that could be used to harmonise headwords of dictionaries, corpus annotations and encyclopaedic entities.

3.2 Meaningfulness, narrative and reproducible research

Rather than only assemble pieces of information in one place, medialatinitas.eu aims to provide whenever possible a relatively exhaustive and coherent narrative of each lemma. As for the exhaustiveness, the variety of the resources employed assures that no crucial level of word description is omitted. Dictionaries, apart from the obvious semantic information, provide also morphological, orthographical, syntactical and pragmatical information. Corpora contribute to the description of frequency, collocational features and computed meaning of a word. They are also a valuable source of knowledge about diachronic evolution of the lemma. Finally, the cultural component is covered by the use of paremiological resources, iconographic evidence (which helps to trace down allegorical sense), thesauri (for example, plant names) etc.

medialatinitas.eu should provide its users with a coherent and meaningful narrative for three reasons. Firstly, it is a reaction to the growing popularity of automatically compiled on-line content aggregators in which the very fact of juxtaposing multiple resources seems often to suffice as their raison d'être. Such a seemingly objective form of data presentation, at the same time, obscures the fact that the composition itself is already an interpretation. Secondly, the presence of contextualising, explicative or interpretive commentary seems to be what may distinguish human-oriented research applications from the popular, yet mainly machine-oriented resources, such as WordNet or BabelNet. Thirdly, medialatinitas.eu is also an exercise of a new form of lexicographic discourse in the era of linked linguistic data.

At the most basic level, the narrative “glue” is generated in the form of short introductory phrases which precede each widget or widget group. Being functionally equivalent to the headers, they do not add any substantial information; instead they, first, enable users to get instant insight into what linguistic or cultural phenomenon is represented in a specific section of the page and, second, make possible reading the whole page as a continuous text.

Aside from that, the narrative is built across the page by means of three other devices:

1) graphical and textual hints;

2) explicative and interpretative passages;

3) dynamically generated reports.
Graphical and narrative hints that the users find all over the interface indicate quality, scope and completeness of the presented data. Since *medialatinitas.eu* is to be a research tool, the user needs to be able to assess, first of all, whether they may safely draw conclusions from the gathered resources, and, secondly, whether insights offered in visuals, such as maps or charts, are of more than decorative value. To this goal, graphical signs and corresponding labels have been employed throughout the page, which signal:

- whether a widget was built on a resource of high, low or unknown quality;
- which chronological and geographical dimension a specific resource represents and
- whether it covers some phenomenon fully or only partially.

In a practical case of an excerpt from the *LMILP*, the quality, scope and coverage would be set *resp.* as “high (academic)”, “10-15\(^{\text{th}}\) c., Poland”, and “full”, whereas in the case of an OCR-ised text they would be specified as “low (OCR)”, “6-12\(^{\text{th}}\) c., Europe” and “partial”.

![Figure 6: PCA chart: computed co-occurrences of the lemma *aqua* ‘water’ in the *Patrologia Latina* corpus (generated with A. Guerreau’s R script).](image)

In the *medialatinitas.eu* visualisation widgets are accompanied by a short passage whose role is to explain what procedures have been applied to yield the results and to help with their interpretation. There are at least two reasons for providing such an explanation. First, *medialatinitas.eu* sticks with the reproducible research paradigm. At any time, the user may learn not only how specific visualisation was generated, but also explore its theoretical background. Second, some less standard forms of data presentation simply do not suffice without commentary text, if they are to be more than a decorative device. Whereas a barplot illustrating diachronic distribution of a specific word is relatively self-explanatory, the same cannot be said about the
boxplots, PCA charts (Figure 6) or co-occurrence barplots (Figure 7) which should be accompanied by a supplementary text if they are not to overwhelm a less advanced user.

Figure 7: Barplot representing computed co-occurrences of the lemma *aqua* ‘water’ in the *Patrologia Latina* corpus (data fetched from an R session exposed with OpenCPU API; the chart generated with the help of the *d3.js* library).

Hints are, therefore, provided as to how one can interpret the geometric properties of the chart, such as distance between the points, width of the boxplot, and so on. In the case of the co-occurrence barplot, for instance, apart from the information provided in the legend, one may learn that the selected coefficient promotes some type of collocates or that the intensity of the colour of the bar corresponds to the absolute frequency of the co-occurring word in the specific corpus.

Finally, the paradigm of reproducible research is further promoted by enabling users to download complete reports from their queries. Since the reports are available not from the main, but from the extended, view page built with *shiny R* and *OpenCPU*, they will not be explained here in more detail.

4. Conclusion

4.1 Previous research

The integrative, holistic approach to word meaning has been a central idea of philology since its Greek origins, but is also accentuated in modern, cognitive lexical semantics.\(^7\) The architecture of the application presented in this paper, which is a hybrid tool (Granger, 2012), benefits from research on mashups and content aggregation (Daniel & Matera, 2014). *medialatinitas.eu* makes heavy use of visualisation techniques and other alternative ways of lexicographic data

---

\(^7\) Geeraerts (1988; 2009) is one of few researchers to notice the link between the historical-philological and cognitive semantics.
representation and in that respect it builds on recent research into linguistic data visualisation (Theron & Fontanillo, 2013). The notion of reproducible research in scientific computing has recently gained interest, as easy to use R packages such as knitr (Xie, 2014) were made available. Although, at the current stage, medialatinitas.eu adopts a lightweight, UI-based model of data integration, further work will certainly focus on closer data integration following the LLOD model (Chiarcos et al., 2013). Already in its present form, though, the application exploits existing Semantic Web resources, such as BabelNet, Europeana, Getty Thesaurus of Geographical Names, Pelagios Project etc. Integration of the lexicographic resources is promoted and stimulated to an unprecedented extent within the European Network of e-Lexicography (ENeL) of which the authors of the present paper are members.

Interest in dictionary applications that follow the aggregator or mashup model seems to be rapidly growing in recent years, with such eminent examples as Dictionary.com, FreeDictionary, or Wordnik. Regardless of the reasons for it, the aforementioned resources usually offer aggregation of the dictionary content within a user-friendly interface equipped with an efficient query engine. Yet, in the majority of cases, they reuse popular general dictionaries, do not offer any further commentary concerning fetched data and in particular they do not inform about the credibility of the resources. This makes them hardly usable as research tools. The situation is slightly different when one takes into account such aggregators as Dictionnaire vivant de la langue française. One will find here juxtaposed the excerpts from renowned lexicographic works (e.g. TLFi), but also a selection of corpus and web quotations, as well as charts illustrating the changing frequency of the word. The DVLF seems to adopt the same design as that of Logeion which, apart from aggregating Latin dictionaries, presents additional information for each lemma based on the Perseus Digital Library: a list of authors who frequently use the word and a small selection of co-occurring terms. medialatinitas.eu differs from the websites mentioned above not only in the general architecture or scope of the integration, but also in the resources employed, use of encyclopaedic data, implementation of complex statistics, visualisation techniques etc. The same properties distinguish medialatinitas.eu also from more general oriented text analysis frameworks such as the Perseus Digital Library which collects a large number of lemmatised Latin and Greek texts of Classical Antiquity and Renaissance. Apart from the already mentioned differences, medialatinitas.eu is principally lemma-, not text-, oriented; therefore, it is expected to be used as a tool for exhaustive analysis of the vocabulary and not as a reading environment. Moreover, medialatinitas.eu employs graphical hints, rich visualisations and mapping; exploits modern academic works rather than older dictionaries or text

---

9 According to the Alexa website ranking, among 20 most viewed dictionary pages there are at least three resources of this kind: The FreeDictionary (the 380th most popular page on the web and the second most popular dictionary after WordReference), SpanishDict (1827th) and Your Dictionary (2116th).
editions; goes beyond in-house resources and uses transparent co-occurrence and frequency measures. Unlike the *Perseus*, it makes a clear distinction between text collection and linguistic corpus and contains a great deal of medieval texts. Contrary to the *Perseus*, which has not seemed to evolve much over the last few years, *medialatinitas.eu* is conceived as a modular, open to extension, lightweight application.

4.2 Further development

The future development of the *medialatinitas.eu* will focus on four main objectives. First, a more appropriate model of linguistic data integration needs to be adopted in order to better deal with the diachronic evolution of Latin vocabulary and with conflicting annotations of linguistic resources. Apart from a faster and more direct search, closer integration should also lead to more sophisticated processing of the user’s input. Currently, the search is limited to lemmas only and as such it requires the user to have a rather good knowledge of the Latin language. Secondly, more data should be hosted locally which should help to lower the query and page display times. It is also desirable, because the external APIs (the *BabelNet HTTP API* is one example) often limit the number of queries that can be sent from a single IP address. Thirdly, new widgets should be added and the existing ones need to be constantly improved. The system of graphical hints should be refined and more techniques of data representation and computation should be suggested. Finally, a community of users and content providers needs to be expanded.

5. Acknowledgements

Work on the present paper has been funded by:

1) the “Young Researcher Grant” of the Polish Ministry of Science and Higher Education attributed to Krzysztof Nowak by the Institute of Polish Language (Polish Academy of Sciences);

2) the “Soutien à la mobilité internationale” grant attributed to Bruno Bon by the Institut des Sciences Humaines et Sociales (Centre National de la Recherche Scientifique).

The paper has greatly benefited from the discussions and workshops of the *ENel COST Action* in which both authors have had the opportunity to participate.

The authors would also like to thank Renaud Alexandre (IRHT CNRS) for his remarks.
